Summary

Motivation: The Corona Crisis

- ▶ Using the years 2020–2023, marked by the Corona crisis, we can illustrate many macroeconomic issues with real-world examples.
- ▶ Private consumption and GDP fell — at the same time, government spending increased.

How Economists Analyze Economic Policy Problems

Using (mathematical) models:

- ▶ Precision of the problem, transparent assumptions, consistent analysis.
- ▶ Clear indication of model assumptions and causal relationships.
- ▶ Basic concept of an economic model:
 - ▶ Mathematical functions describe causal relationships
 - ▶ Model assumptions influence both causality and dynamics
 - ▶ Exogenous (independent) and endogenous (dependent) variables
 - ▶ Model parameters
- ▶ The model shows dynamics and is suitable for comparative statics.
- ▶ Comparison of model statements with empirical analysis.

Summary

Empirical Macroeconomics

- ▶ Empirical analyses require experiences and real events.
- ▶ In macroeconomics there are no artificial laboratory data to test hypotheses. One must make do with the available data based on past real situations.
 - ▶ Example: Did the Hartz reforms reduce German unemployment?
- ▶ Important econometric insights are based on
 - ▶ Time series data
 - ▶ “Natural experiments” (e.g. German reunification)
 - ▶ Comparisons between countries (or states, cantons)

Summary

Learning Objectives and Literature of the 2nd Lecture

- ▶ Learning Objectives:
 - ▶ The economy in the short-run
 - ▶ Idea and construction of a macroeconomic model
 - ▶ Components of gross domestic product (GDP) and their determinants
 - ▶ Consumption theories according to Keynes and Friedman
 - ▶ Derivation of the IS curve for the IS-LM model
- ▶ Literature: Textbook by Blanchard: Chapter 3, 5.1, 14.1 & 14.2

GDP over Time & Course Structure

- ▶ In the long run GDP follows a (hopefully rising) path.
- ▶ At any given time there is a GDP value on the trend line ($Y_{n,t}$).

- ▶ We first examine short-term fluctuations (→ Lectures 2 to 4).
- ▶ Then, we determine $Y_{n,t}$ at a given time t (→ Lectures 5 to 7).
- ▶ Finally, we analyze the trend of $Y_{n,t}$ (→ Lectures 10 to 11).

Summary

The Economy in the Short-Run

- ▶ In lectures 2, 3 and 4 we focus on the *short-run*.
 - ▶ Short-run (< 5 years), medium-run (5-10 years), long-run (> 10 years).
 - ▶ The subdivision is based on how quickly economic processes unfold.
 - ▶ Each requires a different perspective and economic analysis tools.
- ▶ Economic variables behave differently in the short-run than in the long-run.
 - ▶ Example: Government spending is increased. Short-term GDP increase; the long-term effect is much less clear.
 - ▶ In the short-run, we ignore resource constraints and analyze economic fluctuations. Prices and wages are rigid in the short-run. In the medium-run, price increases can lead to inflation, for example.

Summary

Schedule Lectures 2–4

- ▶ We want to analyze the economy within the framework of an economic (theoretical) model.
- ▶ Economic models consist of mathematical equations:
 - ▶ Advantage: assumptions and causal relationships clearly described, unlike the verbal 'anything goes' approach.
 - ▶ “Too many economists fall in love with the math and forget its instrumental nature.” — Dani Rodrik (Economics Rules, p.35)
- ▶ Abstract and simplify economic models.
 - ▶ “A model that takes into account the whole colorfulness of reality, wouldn't be any more useful than a one-to-one map.” — Joan Robinson

Discussion

Summary

Schedule Lectures 2–4 (continued)

- ▶ We use the well-known IS-LM model:
 - ▶ As simple as possible, but not too simple.
 - ▶ We essentially need: goods market, financial market
 - ▶ We leave out for now: labor market, stocks, foreign countries, ...
 - ▶ Goods market in equilibrium (IS curve): supply and demand
 - ▶ Financial market in equilibrium (LM curve): supply and demand
- ▶ We describe supply and demand with simple mathematical formulas.
- ▶ Goal: Understanding model, applying model, questioning model.

An Example

- ▶ Japan raised the value added tax from 8% to 10% as of Oct 1, 2019.
 - ▶ On October 8th, the *Financial Times* wrote:
“Japan data point to bigger than expected hit from sales tax rise
Drop in spending adds to pressure on central bank to ease monetary policy”
 - ▶ How can the effects of a tax increase be explained?
 - ▶ Japan's government increased VAT knowing the short-term negative effects.
The goal was to reduce the public deficit.
How is the measure to be assessed in the medium-term?
- ▶ In analogy to other sciences, macroeconomics attempts to depict causal causal relationships using (mathematical) models.

The Economy in the Short-Term

- ▶ With annual fluctuations in economic activity, the interrelation between production, income and demand is central to macroeconomic understanding:
 - ▶ Changes in demand lead to adjustments in production.
 - ▶ Adjustments in production trigger changes in income.
 - ▶ Changes in income cause changes in demand.
- ▶ In the analysis of the goods market we therefore focus on
 - ▶ Demand for goods, production, and income.
 - ▶ As seen in lecture 1, all three correspond to GDP.

Components of Gross Domestic Product (GDP)

- ▶ The GDP can be determined in three ways:
 - ▶ Production approach
 - ▶ Income approach
 - ▶ Expenditure approach
- ▶ $GDP = Y = C + I + G + NX$
 - ▶ C: Private consumption of goods and services
 - ▶ I: Private investment
 - ▶ G: Government purchases of goods and services
 - ▶ $NX = X - IM$: Net exports (exports minus imports)
- ▶ What factors determine C, I, G? (assumption: closed economy, i.e. $X = IM = 0$)

Swiss GDP Growth over Time

► Consumption fluctuates much less than GDP.

Derivation
Discussion

Summary

Theories on Consumption

- ▶ How is the consumption C determined?
- ▶ Idea of the Keynesian consumption function:
 - ▶ Consumption is based only on current disposable income.
 - ▶ The propensity to save/consume is postulated from aggregated data (there is no micro-foundation).
- ▶ Idea of the permanent income hypothesis:
 - ▶ Households with a longer-term planning horizon choose consumption in such a way that that an intertemporal utility function is maximized (as a result we see consumption smoothing).
- ▶ We focus here on the Keynesian approach.
- ▶ → Further discussion in the tutorials

Components of GDP — Consumption

- ▶ Consumption function: $C(Y_D)$ with Y_D as disposable income $Y_D = Y - T$:
 - ▶ $C = C_{(+)}(Y_D)$ describes an economic context as a function,
 $C'_{(+)}(Y_D) > 0$ marginal propensity to consume
 - ▶ Note: T = Taxes – transfer payments
- ▶ As linear function: $C = c_0 + c_1 Y_D = c_0 + c_1 (Y - T)$
 - ▶ Two parameters:
autonomous consumption c_0 and propensity to consume $0 < c_1 < 1$

Components of GDP — Consumption (graphical)

► Graph:

Keynesian Consumption Function in the Data

- Based on Swiss data for income (Y_D) and consumption (C) the result is an estimated function $C = \hat{c}_0 + \hat{c}_1 Y_D = 68 + 0.8 Y_D$.

Discussion

Summary

Keynesian Consumption Theory: Discussion

- ▶ Every economic model requires simplifying assumptions — it is important (after understanding of the model) to critically examine them.
- ▶ Fundamental critique of the Keynesian consumption function: it is postulated and not derived (not micro-founded).
- ▶ Important factors not considered:
 - ▶ Income shifts over the life cycle
 - ▶ Consideration of future income (and taxes)
 - ▶ Savings, interest rate
 - ▶ Wealth

Permanent Income Hypothesis

- ▶ The permanent income model describes how households, taking into account their budget constraints, determine their consumption path over time in order to maximize their utility.
- ▶ Elements of the model:
 - ▶ Lifetime income: all present and future income.
 - ▶ Utility function: Consumption and leisure generate utility.
 - ▶ Intertemporal budget constraint:
Households cannot spend more than they earn.
 - ▶ Optimization within the constraints (→ *tutorials*)

Components of GDP — Investment

- ▶ Three components of private investment: investment in equipment by firms, investment in construction, changes in inventories
- ▶ Private investment is important for two reasons:
- ▶ (1) Part of GDP: $Y = C + I + G + NX$
 - ▶ Investments explain the level and (short-term) fluctuations in output.
 - ▶ Investment is much more volatile than consumption
→ household consumption smoothing
- ▶ (2) Increase the stock of productive capital
 - ▶ $K_{\text{tomorrow}} = K_{\text{today}} + I - \text{Depreciation}$
 - ▶ Investment central to long-term economic growth → Lecture 10.

Components of GDP — Investment (continued)

- ▶ What determines the level of private investment?
- ▶ (1) The interest rate
 - ▶ Companies have many potential investment projects with different returns (*returns-on-investment, RoI*).
 - ▶ Every project has a net present value (*net present value*):
$$NPV = CF_0 + CF_1/(1+i) + CF_2/(1+i)^2 + CF_3/(1+i)^3 + \dots$$
 - ▶ CF_0 Investment today = (negative) cash flow
 - ▶ $CF_1, CF_2, CF_3, \dots$:
Future earnings (in case of uncertainty: expected earnings)
 - ▶ A lower interest rate makes more projects profitable (→ opportunity costs)
- ▶ (2) The level of production:
 - ▶ To be able to produce more, additional machines are necessary.

Components of GDP — Investment (continued)

- ▶ We summarize both aspects mathematically: $I = I\left(\underset{(+)}{Y}, \underset{(-)}{i}\right)$
- ▶ In contrast to Blanchard, you often find $I(i)$.
- ▶ The model could be supplemented by other factors:
 - ▶ Expectations about the future ($\rightarrow$ PMI)
 - ▶ Risk preferences
- ▶ In the textbook investments are sometimes fixed, i.e. they are assumed to be exogenous: $I = \bar{I}$.
This simplifies the analysis.
 - ▶ Endogenous variables: depend on other variables in the model.
 - ▶ Exogenous variables: not explained in the model.

Components of GDP — The State

- ▶ GDP: $Y = C + I + G + NX$
- ▶ How can the state act influence GDP?
 - ▶ Direct and indirect taxes $\rightarrow T$
 - ▶ Transfer payments (e.g., unemployment benefit) $\rightarrow T$
 - ▶ Government spending on goods and services $\rightarrow G$
- ▶ Decisions on government spending, G , and the amount of taxes and transfers, T , are called fiscal policy.
- ▶ We treat G and T as exogenous variables.

Equilibrium on the Goods Market

- ▶ An equilibrium on the goods market can only be achieved if if the production of goods, Y , equals the demand for goods, Z :
 - ▶ $Y = Z = c_0 + c_1 * (Y - T) + I(Y, i) + G$ (assumption: $X = IM = 0$)
 - ▶ In equilibrium, production Y (left side of the equation) equals demand (right side of the equation).
 - ▶ Demand in turn depends on income Y ; income in turn is equal to production. Idea: Unused capacities.
 - ▶ Both production and income are denoted by Y .
 - ▶ In practice, Y and Z can differ from each other.

Equilibrium on the Goods Market — Graphical

- ▶ Equilibrium on the goods market with $I = \bar{I}$:
 - ▶ Supply of goods (= production = income = Y) = demand for goods (= Z)
- ▶ Graph (Keynesian cross):

- ▶ Note: the ZZ curve is drawn for a given interest rate.

Equilibrium on the Goods Market — Comparative Statics

- ▶ The demand for goods $Z = (c_0 + I(Y, i) + G - c_1 T) + c_1 Y$ increases if
 - ▶ autonomous consumption (c_0) is increasing
 - ▶ the government spending (G) is increased
 - ▶ taxes (T) are reduced
 - ▶ the interest rate (i) is lower
- ▶ How does the equilibrium change if government spending G increases?
 - ▶ In equilibrium the following applies: $Y = Z = c_0 + c_1 * (Y - T) + I(Y, i) + G$
 - ▶ Let us assume $I = \bar{I}$ and solve the equation for Y :
$$Y = \frac{1}{1-c_1} \left[c_0 + \bar{I} + G - c_1 T \right] \quad \implies \frac{1}{1-c_1} = \text{multiplier}$$
 - ▶ If G increases by 1, Y increases by $1/(1 - c_1) > 1$

Summary

Equilibrium on the Goods Market — Comparative Statics

- An increase in government spending G

- Note: $\Delta Y = 1/(1 - c_1) * \Delta G > \Delta G$.

Intro

Short-Run

Components of
GDP

Consumption

Investments

Government Spending

Equilibrium

The IS Curve

Derivation

Discussion

Summary

How Large is the Multiplier?

- ▶ $\Delta Y = 1/(1 - c_1) * \Delta G > \Delta G$
 - ▶ Valid only for unutilized capacities; hence the amount is often overestimated.
- ▶ Examples: HSG, EU Green Deal, Juncker Plan

Equilibrium on the goods market — Multiplier effect

- ▶ For a given increase in the ZZ curve, the rise of Y depends on how big c_1 is. Why?
 - ▶ If demand increases by 100 CHF, then after n rounds there is an increase in production of 100 CHF multiplied by the following sum:
 $1 + c_1 + c_1^2 + \dots + c_1^n$. (→ geometric series)
- ▶ Numerical example: The state pays 100 CHF for road repair.
 - ▶ Road builder spends (at $c_1 = 0.8$) 80 CHF in a shop and saves 20 CHF.
 - ▶ Retailers spend $80 \cdot 0.8 = 64$ CHF and save 16 CHF.
 - ▶ After 2 rounds a cumulative increase of $100 + 80 + 64 = 244$ CHF.
 - ▶ After all the rounds:
Increase in GDP by 500 CHF (multiplier of $1/(1 - c_1) = 5$).

Derivation of IS curve

- ▶ The IS curve describes the equilibrium on the goods market.
- ▶ The effects of a rise in interest rates on income:
 - ▶ investments are interest-dependent, i.e. $I = I(i, Y)$.
 - ▶ A rise in the interest rate causes investments and thus income to decline. The demand curve for goods shifts downwards.

Derivation of IS curve (continued)

- As interest rates rise, income falls in the goods market equilibrium. The IS curve therefore has a downward slope:

- Above the IS curve: Excess supply on the goods market
Below the IS curve: Excess demand on the goods market
On the IS curve: equilibrium on the goods market

IS-Curve: Investments and Savings

- ▶ Name of the IS curve: Savings = Investments.
- ▶ Investment equals savings:
An alternative approach to the equilibrium on the goods market.
- ▶ Private consumer savings: $S = Y - T - C$
- ▶ GDP equation (excluding exports and imports): $Y = C + I + G$
 - ▶ $S + T + C = Y = C + I + G$
 - ▶ $\implies I = S + (T - G)$ (with trade: $I = S + (T - G) + (IM - X)$)
- ▶ The goods market is only in equilibrium if investment equals savings (the sum of private and state savings).
- ▶ Is S or I the driver? Theory of effective demand (Keynes) versus supply-oriented theories (Say's law, (neo-)classical).

The IS Curve: Summary

- ▶ Implicit IS curve: $Y = C(Y - T) + I(Y, i) + G$ (assumption: $X = IM = 0$)
- ▶ The IS curve depends negatively on the interest rate:
With increasing interest rates, investment demand and total production decreases.
 - ▶ Where does the interest rate come from?
→ Financial Market, LM-curve, Lecture 3
- ▶ Movement along the IS curve:
Interest rate change → Endogenous adjustment of production volume
- ▶ Shifts in the IS curve:
Factors that trigger a decrease (an increase) in the demand for goods at a given interest rate, shift the IS curve to the left (right).
Example: increased government spending.

Summary and Outlook

- ▶ We analyzed the goods market of an economy.
- ▶ The IS curve summarizes the equilibrium on the goods market in the interest/income graph.
- ▶ We will introduce the LM curve in lecture 3.
- ▶ We will then combine IS and LM to discuss the IS-LM model in Lecture 4.
- ▶ Preparation for lecture 3: Slides and chapter 4 & 5.2 of the textbook

Discussion

- ▶ Open questions from the audience?
- ▶ The savings paradox — is saving bad?
 - ▶ Y decreases with increasing propensity to save (i.e. with smaller c_0, c_1)
 - ▶ The higher c_1 the higher the multiplier.

Application to the Current Situation

- Consumer sentiment in Switzerland, calculated by SECO, has continued to recover. What does this mean for the Swiss economy?
